CLMN 79
GI 15 Figure(s).

FIG. 1 shows exemplary Fc dimers that may be derived from an IgG1 antibody. "Fc" in the figure represents any of the Fc variants within the meaning of " ***Fc*** ****domain*** " herein. "X1" and "X2" represent peptides or linker-peptide combinations as defined hereinafter. The specific dimers are as follows:

A: Single disulfide-bonded dimers. IgG1 antibodies typically have two disulfide bonds at the hinge region between the constant and variable domains. The ***Fc*** ****domain*** in FIG. 1A may be formed by truncation between the two disulfide bond sites or by substitution of a cysteinyl residue with an unreactive residue (e.g., alanyl). In FIG. 1A, the ***Fc*** ****domain*** is linked at the C-terminus of the peptide.

B: Doubly disulfide-bonded dimers. This ***Fc*** ****domain*** may be formed by truncation of the parent antibody to retain both cysteinyl residues in the ***Fc*** ****domain*** chains or by expression from a construct including a sequence encoding such an ***Fc*** ****domain***. In FIG. 1B, the ***Fc*** ****domain*** is linked at the C-terminus of the peptide.

C: Noncovalent dimers. This ***Fc*** ***domain*** may be formed by elimination of the cysteinyl residues by either truncation or substitution. One may desire to eliminate the cysteinyl residues to avoid impurities formed by reaction of the cysteinyl residue with cysteinyl residues of other proteins present in the host cell. The noncovalent bonding of the ***Fc*** ***domains*** is sufficient to hold together the dimer. Other dimers may be formed by using ***Fc*** ***domains*** derived from different types of antibodies (e.g., IgG2, IgM).

FIG. 2 shows the structure of additional compounds of the invention. FIG. 2A shows a single chain molecule and may also represent the DNA construct for the molecule. FIG. 2B shows a dimer in which the linker-peptide portion is present on only one chain of the dimer. FIG. 2C shows a dimer having the peptide portion on both chains. The dimer of FIG. 2C will form spontaneously in certain host cells upon expression of a DNA construct encoding the single chain as shown in FIG. 3. In other host cells, the cells could be placed in conditions favoring formation of dimers or the dimers can be formed in vitro.

FIG. 3 shows exemplary nucleic acid and amino acid sequences (SEQ ID NOS: 1 and 2, respectively) of human IgG1 Fc that may be used in this invention.

FIG. 4 shows the calcemic response of normal mice to ***PTH*** -(1-34) and to ***PTH*** -(1-34)-Fc. Mice were challenged with vehicle (PBS, X-), or with ***PTH*** -(1-34) (open symbols) or with ***PTH*** -(1-34)-Fc (closed symbols). Doses were 156 nmol/kg (circles), 469 nmol/kg (triangles) or 1,560 nmol/kg (squares). Data represent group means, n=6 mice/group.

FIG. 5 shows that (Asn10,Leu11) ***PTHrp*** -(7-34)-Fc inhibits the calcemic response of normal mice to ***PTHrp***. Normal male mice were injected SC with vehicle (PBS, circles) or with human ***PTHrp*** -(1-34) at 0.5 mg/kg (squares). ***PTHrp*** -challenged mice were then immediately injected SC with (Asn10,Leu11) ***PTHrp*** -(7-34)-Fc at 10 mg/kg (triangles) or 30 mg/kg (diamonds). Data represent group means, with an n of 6 mice/group.

FIG. 6 shows the effect of (Asn10,Leu11) ***PTHrp*** -(7-34)-Fc on chronic hypercalcemia induced by ***PTH*** -(1-34)-Fc. Normal male mice were challenged once by SC injection with ***PTH*** -(1-34)-Fc (30 mg/kg) (open circles), or with vehicle (PBS, open squares). Some ***PTH*** -(1-34)-Fc-challenged mice were treated once, at the time of challenge, with (Asn10,Leu11) ***PTHrp*** -(7-34)-Fc at 10 (closed triangle), 30 (closed circle), or 100 mg/kg (closed square). All doses of (Asn10,Leu11) ***PTHrp*** -(7-34)-Fc caused a significant suppression of ***PTH*** -(1-34)-Fc-mediated hypercalcemia. Data represent means \pm SEM, n=5 mice/group.

FIG. 7 shows CAMP accumulation in ROS 17/2.8 rat osteoblast-like cells. Cultures were treated with the phosphodiesterase inhibitor IBMX and then challenged for 15 minutes with various ***PTH*** fragments. CAMP was measured by ELISA.

FIG. 8 shows the effects of single treatments on clinical chemistry. Peripheral blood was obtained daily for 3 days following single subcutaneous injections of the indicated compounds. FIG. 8A shows total serum calcium; FIG. 8B, alkaline phosphatase (AP), a marker of osteoblast activity; FIG. 8C, tartrate-resistant acid phosphatase (TRAP), a marker of osteoclast activity, and FIG. 8D, AP:TRAP ratio, an index of relative osteoblast: osteoclast activity.

FIG. 9 shows the effects of ***PTH*** constructs on bone mineral density. Peripheral quantitative computed tomography (pQCT) was performed on the proximal tibial metaphysis of mice on day 15, after injections of ***PTH*** constructs on day 0, 5 and 10.

FIG. 10 shows the effect of twice-weekly ***PTH*** -(1-34)-Fc versus daily ***PTH*** -(1-34) on tibial, trabecular, and cortical bone mineral density (BMD). Daily ***PTH*** (***PTH*** -(1-34)) was given at 80 μ g/kg/day (20 nmol/kg/day).

FIG. 11 shows the effects of twice-weekly treatment on BMD and serum calcium in aged ovariectomized (OVX) rats. Eleven months after OVX, rats were treated twice per week with phosphatebuffered saline (PBS, vehicle) or with APD (0.5 mg/kg) or with ***PTH*** -(1-34)-Fc (50 nmol/kg). DEXA was performed weekly. Blood was drawn 24 hours after the second weekly injection, when the calcemic effects of ***PTH*** -Fc are typically maximal.

FIG. 12 shows the effect of a single subcutaneous injection of ***PTH*** -(1-34)-Fc into OVX cynomolgus monkeys. Monkeys were injected with ***PTH*** -(1-34)-Fc at doses of 1-30 μ g/kg (n=1/group) or 100-1000 μ g/kg (n=2/group). Serum was analyzed for total calcium. The dotted line indicates the threshold for hypercalcemia, based on an elevation of calcium greater than three standard deviations above the normal mean, on

two or more consecutive timepoints.
